2012
2016

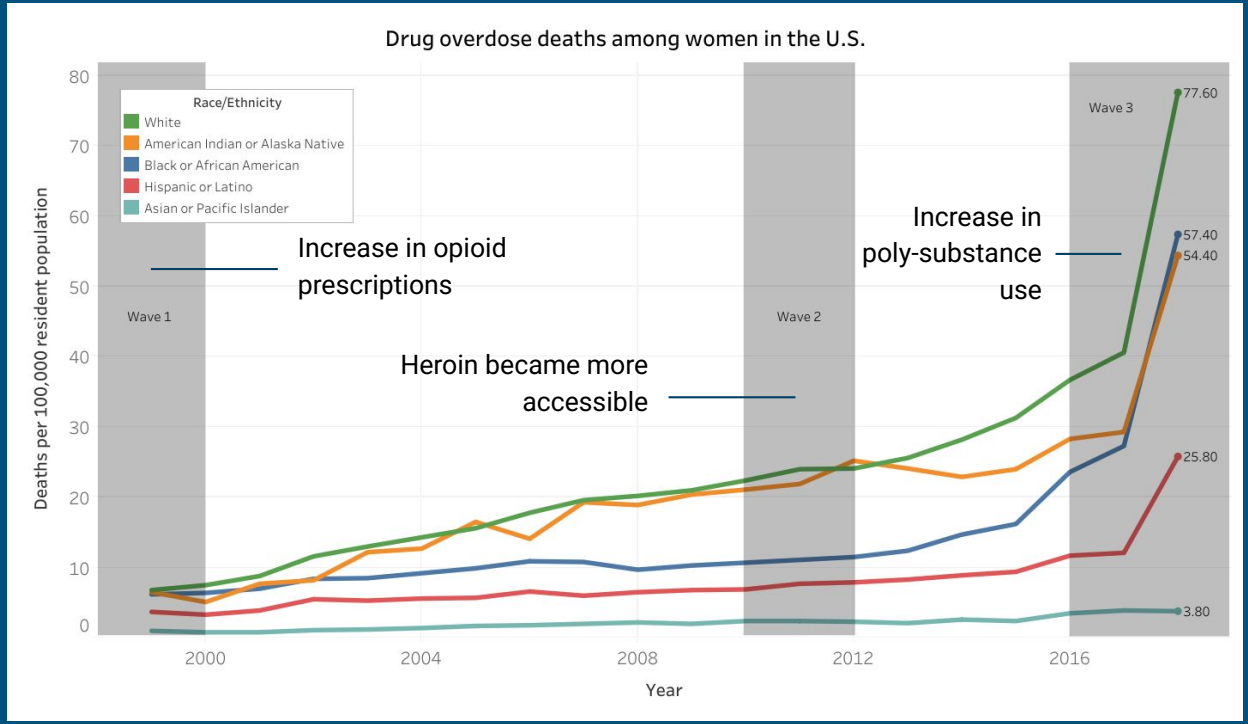

Background Research

- Overdose deaths have increased for both genders from 1999-2017
  - Men: 225%
  - Women: 270%
- Until 1993, women who could become pregnant were excluded from clinical trials
- Clinical trial data on women was not representative of the full female population
  - Incomplete data on sex differences
  - Less data overall for women
- OxyContin would be released in 1995, enabling the start of the opioid epidemic (wave 1)

Precise Message

All women are affected by the opioid epidemic, with the impact varying across racial communities.

- Misrepresentation reinforces stigmatization
- Proper reflection enables targeted strategies

Limitations

- Data after 2017 was reported differently
- Lack of intersectionality
  - e.g. Data for hispanic women and women age 65+ separately, but not together
  - Visualized data is age-adjusted
- Geographic information found in different dataset
- Specific drug type(s) found in different dataset

Revisions & Future Work

- Initial focus on sudden increase of deaths (after 2016) seen in most women of color
- Additional research provided a bigger picture of the epidemic
    - Message would change to look at the entire population of women in the U.S.

- Recent data can be analyzed with proper preprocessing upon joining the two datasets
    - Better reporting on drugs involved, including polysubstances
    - States involved are specified alongside demographics

Dataset & Resources

All women are affected by the opioid epidemic, with the impact varying across racial communities.
